Mr Munch: 3-minute pitch script

Encode 2026 · Armando Medina (Backend) · Marco Germanier (Data)

Running order

#	Slide	Speaker	Time	Ends at
1	Eat out without the fear	Marco	15 s	0:15
2	Eating out shouldn't be a gamble	Marco	30 s	0:45
3	From craving to a confirmed table	Armando	20 s	1:05
4	Live demo: Let's book dinner	Armando	60 s	2:05
5	MongoDB Atlas is the shared brain	Marco	25 s	2:30
6	MongoDB features in our code	Marco	10 s	2:40
7	Honest, private and in your control	Armando	12 s	2:52
8	Eat out without the fear (close)	Marco	8 s	3:00

About 400 spoken words in total. The demo is the only part allowed to run over. If it does, cut slide 7 short; slide 6 can also just stay on screen for Q&A.;

Script

1 · Eat out without the fear

MARCO · 0:00–0:15

Hi, we're Mr Munch, your AI dining concierge for people with allergies and dietary restrictions.

I'm Marco, I'm allergic to shellfish. Armando is vegan. So every dinner out starts with the same question: *what can we actually eat here?*

2 · Eating out shouldn't be a gamble

MARCO · 0:15–0:45

We're not alone. **2.4 million** adults in the UK have a clinically confirmed food allergy. **One in a hundred** people has coeliac disease. And hospital admissions for food anaphylaxis **tripled** in twenty years.

Yet menus rarely tell you what's in a dish. So you call the restaurant, you decode the menu, and you hope the kitchen understood. In a group, everyone has a different rule.

Sources on the slide: FSA Patterns and Prevalence of Adult Food Allergy (2024); Coeliac UK; Baseggio Conrado et al., BMJ 2021.

3 · From craving to a confirmed table

ARMANDO · 0:45–1:05

Mr Munch does the research for you in four steps.

Find: nearby restaurants from Google Maps, cross-checked with OpenStreetMap's vegan and vegetarian tags. **Read:** the menu, from the website or a photo of the specials board. **Check:** every dish against the UK's 14 major allergens and your diet. **Book:** your Saint agent books the table, after asking you.

4 · Live demo: Let's book dinner

ARMANDO DRIVES · 1:05–2:05

Send to Saint: *“Find us dinner tonight near Shoreditch. Armando is vegan, Marco can't eat shellfish.”*

While it runs (about 45 seconds), talk over it: “First it asks MongoDB Atlas what it already knows: a hybrid search over every dish other users have found. Then Google Maps and OpenStreetMap find vegan-friendly places nearby, and it reads their menus.”

When the answer arrives, point at: the restaurant and its OpenStreetMap vegan tag; the dishes with their allergens; the line saying the kitchen must confirm (**unknown never counts as safe**); and Saint asking permission before booking. Say yes.

Backup: if the call is slow or fails, switch to the recorded run straight away. Rehearse with the same request so the result is predictable.

5 · MongoDB Atlas is the shared brain

MARCO · 2:05–2:30

MongoDB Atlas is the shared brain, and it's **one platform**: no separate vector database, embedding pipeline or search engine. Every dish we read is stored once, and Atlas embeds it automatically with Voyage AI.

Recommendations run a **hybrid search**: $rankFusion combines full-text search, for exact words like prawn or gluten, with vector search, for meaning, and filters out dishes with your allergens. **Voyage reranks** the results. Then the LLM writes the answer **only from the dishes Atlas returned**, so it can't invent a menu.

And it compounds: every menu one person reads makes the next search smarter. We already have more than 630 dishes from real menus.

6 · MongoDB features in our code

MARCO · 2:30–2:40

“And here's exactly how, in our code.” Sweep across the grid: **Atlas Search** for exact allergen words, **Vector Search** with Atlas embedding every dish itself, **$rankFusion** to merge them, **Voyage rerank**, a **2dsphere** index for “near me”, and **upserts on a unique index** so every menu is stored once and shared.

Leave this slide up during Q&A; if judges ask how it works. Code lives in lib/db/hybridSearch.ts, atlas/indexes/, lib/db/persist.ts and lib/services/mongodb.ts.

7 · Honest, private and in your control

ARMANDO · 2:40–2:52

Food allergies are serious, so Mr Munch is **honest**: unknown never counts as safe. It's **private**: we never store anyone's allergies. Your own Saint keeps them. And you stay **in control**: Saint always asks before it messages, books or pays.

8 · Eat out without the fear

MARCO · 2:52–3:00

Mr Munch: find, read, check and book, so people like Armando and me can eat out without the fear. Thank you!

Likely questions

Which MongoDB features do you use?

Atlas Search, Vector Search with Automated Embedding (Voyage voyage-4), Hybrid Search with $rankFusion, and Voyage rerank-2.5 via $rerank. The LLM's final answer is grounded on what Atlas retrieves (RAG). Stream Processing is designed (pipeline in the repo) but not deployed yet.

Can the LLM make up dishes?

No. It only sees the dishes Atlas returned for that restaurant, and the code drops any dish name that wasn't in that list.

How do you know a dish is safe?

We don't claim it is. Dishes are checked against the 14 UK allergens from the menu text; anything unknown is flagged and the restaurant gets a confidence level. For a serious allergy, Saint asks the kitchen.

Do you store users' allergies?

No. Each user's Saint keeps their restrictions and sends them with each request. Atlas only stores knowledge about places: restaurants, dishes, menu photos.

Where does the menu data come from?

Restaurant websites, read through Jina Reader and parsed with OpenAI, photos of menus and specials boards, and OpenStreetMap diet tags. Google Maps finds the places.

Why is it slow?

A fresh area means reading several restaurant websites live (~45 s). Places already in Atlas come back from hybrid search; caching menus is the next optimisation.
